## **Option A**

### **I. Problem**

Better and Tastier Burgers: Given  $n$  kinds of burgers, each burger has two attributes: taste value and health value, select the maximum number of burgers that can be arranged in a line, such that each burger in the line is both tastier and healthier than the one before.

### **II. Analysis**

It is similar to the LIS (longest Increasing sequence) problem.

1. In LIS problem, given array  $A(1 \dots n)$ , we want to find a longest subsequence(not necessarily contiguous) that is strictly increasing. But we only have one attribute. So we define  $X[i]$  = longest strictly increasing subsequence that ends at  $i$ ,  $X[i] = \max \{X[j]\} + 1, j < i \text{ and } A[j] < A[i]$ .

To calculate each  $X[i]$ , we need to traverse from 0 to  $i-1$ , the size of array is  $n$ , so it takes  $O(n^2)$  to calculate all  $X[i]$ . From all these  $X[i]$ , we need to find the MAX value, which takes  $O(n)$  time, therefore, the overall time complexity is  $O(n^2)$ . (Could be  $O(n \log n)$  if using binary search, but more complicate to implement.)

2. Back to Better and Tastier Burgers problem. Now we want to find a longest subsequence that is strictly increasing in both attributes.

However, if we sort these burgers by taste value first, we get a new array which is increasing in taste value, the problem becomes---find a longest subsequence(not necessarily continuous) that is strictly increasing in health value, which is exactly the same as LIS problem.

Steps:

1. QUICKSORT the array by taste value in  $O(n \log n)$  time.
2. Compute the  $X[i]$  of the new array in  $O(n^2)$  time.
3. Optional step: use a new array  $S[i]$  to save the intermediary result  $j \rightarrow \max \{X[j]\} + 1, j < i \text{ and } A[j] < A[i]$ ,  $S[i]$  is used for printing the result.
4. Find the largest value of all  $X[i]$ .
5. Return  $\max \{X[i]\}$ .

The time complexity is :  $O(n^2)$ .

### **III. Coding**

Algorithm consists of three funtions: 1. QUICKSORT,  
2. Modified version of LIS.  
3. function for printing the result.

### **IV. Result**

| n       | Experimental Result | Theoretical Result | Scaling Constant | Adjusted Theoretical Result |
|---------|---------------------|--------------------|------------------|-----------------------------|
| 1000    | 4.47214             | 1000               | 0.00245465       | 2.45465                     |

| 20000   | 49.5681             | 20000              | 0.00245465       | 49.093                      |
| average | 25.773779           | 10500              | 0.00245465       |                             |

The experimental result is the square root of runtime, as we conclude the time complexity of Better and Tastier Burgers algorithm is  $O(n^2)$ , the  $\sqrt{\text{runtime}}$  should be linear in terms of  $n$ , and the graph supports this conclusion: the experimental result matches well with adjusted theoretical result, which is a straight line overall.
